311 – Numerical Computations Lab 7: Numpy Arrays/2D Arrays & Solving Systems of Linear Equations

PreLab) List comprehension in Python:

```
a=[ x*2 for x in range(4)]

print(a) #[0, 2, 4, 6]

b=[ x+1 for x in a]

print(b) #[1, 3, 5, 7]

c=[x**2 for x in a if x %4 ==0] #[0,16]
```

SO:

```
L= input("Enter integers").split()
L= [ int(x) for x in L]
print (L)
```

will convert a list of strings to list of integers

A) The NumPy arrays are homogeneous, this makes any operation on array elements very fast.

import numpy as np
ar = np.array([13,13,'a'])
Output:
['13 ['] '13' 'a']
======================================
b = np.array([13, 13, 3.5])
print(b)
Output:
[13. 13. 3.5]
=======================================

B) Two Dimensional arrays in Numpy import numpy as np

ar = np.array([[9,2,-5], [3,4,-2], [-9,5,-3]])

print(ar)

Output:

[[92-5]

 $[3 \ 4 \ -2]$

[**-9 5 -3**]]

> Slicing matrices in Numpy:

import numpy as np

arr = np.array([[1, 2, 3, 4], [9, 7, 6, 2], [4, 5, 2, 1]])

print(arr[0:2, 1:4])

output:

 $[[2 \ 3 \ 4]]$

[7 6 2]]

Some Numpy function that we will need:

import numpy as np

```
arr = np.array([1, 2, 3, 4, 5])
print(arr)
arr = np.array([[1, 2, 3], [4, 5, 6]])
print(arr)
print(arr[0])
a = np.zeros(3)
print(a)
b = np.ones((2,4))
print(b)
print(b.shape)
print(b.shape[0])
print(b.shape[1])
print(b.size)
c = np.full((3,3),7)
print(c)
[[1, 2, 3], [4, 5, 6]])

```

```
Remark: In Python,

L = [0]* 5

print (L)

will print: [0, 0, 0, 0, 0]
```

```
[1 2 3 4 5]
[[1 2 3]
[4 5 6]]
[1 2 3]
[0. \ 0. \ 0.]
[[1. 1. 1. 1.]
[1. 1. 1. 1.]]
(2, 4)
4
8
```

[[7 7 7]

[7 7 7]

[7 7 7]]

A) How to read a (square) matrix in Numpy:

L = input("Enter matrix A elements: ").split()
L = [float(x) for x in L]
n = int(sqrt(len(L))) #or you can ask for n from user
A = np.array(L).reshape(n, n)
print(A[0][0]) #print an element from matrix

Q1: Using Numpy: write a program that reads a matrix (read its dimension at start) and prints the sum of each row and each column.

Example:

Enter number of rows: 2

Enter number of columns 3

Enter 6 matrix elements: 352184

Sum of row 0=10

Sum of row 1=13

Sum of column 0=4

Sum of column 1=13

Sum of column 2=6

D) Operations on Matrices in Numpy:

E) Solving a linear system:

```
import numpy as np
a = np.array([[1,2,-3], [2,-5,4], [5,4,-1]])
b = np.array([-3,13,5])
x = np.linalg.solve(a, b)

print(a)
print(b)
print(b)
print(x)
print(np.allclose(np.dot(a, x), b))
```

```
[[ 1 2 -3]
[ 2 -5 4]
[ 5 4 -1]]
[-3 13 5]
[ 2. -1. 1.]
True
```

```
F) !!! Singular Matrix!!! import numpy as np
```

```
    a = np.array([[2,4], [3,6]])
    b = np.array([5,17])
    x = np.linalg.solve(a, b)
```

print(x) # !!!! Singular Matrix

```
How to protect against that:
if (np.linalg.det(a)==0):
    print("Singular")
else:
    print("Not Singular")
```

Q2) Write a python program that reads the elements of a square matrix A (assume a perfect square number of inputs), and the b vector (assume correct size), and solve the system: Ax=b.

If the matrix is singular, print "No Unique Solution".

Otherwise print the solution: x.

Assume no error in number of inputs.
